#### Abstract

The specific and non specific inter molecular interactions are sensitive to composition, temperature and presence of different functional groups in the mixture under investigation. Group contribution methods are powerful tools for the prediction of thermodynamic and transport properties of liquid mixtures, for studying the excess molar volume and deviation function in the viscosity. In order to investigate the presence of specific and non specific interactions between the constituent molecules of binary mixtures of Cyclohexane with some Protic and aprotic solvents for measurement of densities and viscosities as the function of mole fractions are carried out. From the measured values excess molar volume and deviation in viscosity is calculated.

Keywords: Excess volume, Deviation in viscosity, Molecular interactions.

## INTRODUCTION

Thermodynamic and transport properties of liquid mixtures have been extensively used to study the departure of a real liquid mixture behaviour from ideality ${ }^{1,2}$ which leads to the intermolecular interaction between the components present in liquid mixtures ${ }^{3,4}$. Alcohols are highly polar in nature and hence form azeotropes easily. Ethanol forms azeotropes with Cyclohexane at 337.8 K while propanol forms at 347.7 K . Thermodynamic study used for understanding the different types of intermolecular interactions like dipole-dipole ${ }^{5}$, dipole- induced dipole ${ }^{6}$ in polar-polar ${ }^{7}$ and polar-non polar ${ }^{8}$ systems. In the present paper work, density and viscosity are determined for the binary systems of Cyclohexane with some protic and aprotic solvents at room temperature from these excess parameters are calculated over entire temperature range of composition.

## EXPERIMENTAL DETAILS

All the chemicals were used of AR grade having purity more than $99 \%$ were directly used. Purity of Solvents Cyclohexane (CH), Ethanol (ET), Praopan-1-ol (PR), Butan-1-ol (BUT), Ether (ETH), Tetrahydrofuran (THF), Toluene(TE), m-Xylene (m-Xy) and N , N , Dimethylformamide (DMF) was checked by comparing the experimental values of densities $(\rho)$ and viscosities $(\eta)$ from literature (Table 1). Our experimentally calculated densities and viscosities of chemicals were well matched with reported values in the literature. Binary mixtures were prepared by mixing of known mass of each liquid in air tight, stoppered glass bottle. The masses were recorded on digital balance (SHIMADZU, AUX 220) having an accuracy of $\pm 1 \times 10^{-4} \mathrm{~g}$. A bicapillary pyenometer with a bulb volume of 15 CC was chosen ${ }^{9}$ for determination of densities of pure liquids and mixtures. The viscosities were measured using Ubbelodhe Viscometer ${ }^{10}$ calibrated
with conduction water. The accuracy of viscosity measurement was 0.001 mpas . An electronic digital stop watch with accuracy of $\pm 0.01$ Second was used for flow time measurement.
The experimental values of densities and viscosities at 301 K over the entire temperature range composition for various binary mixtures are tabulated in table.2. The $\mathrm{V}^{\mathrm{E}}$ is calculated from the experimental data using the relation ( $\mathrm{V}^{\mathrm{E}}$ - Excess Molar Volume)

$$
\begin{equation*}
V^{\mathrm{E}}=\mathrm{X}_{1} \cdot \mathrm{M}_{1}\left\lceil\frac{1}{\rho_{\mathrm{M}}}-\frac{1}{\rho_{1}}\right\rceil+\mathrm{X}_{2} \cdot \mathrm{M}_{2}\left\lceil\frac{1}{\rho_{\mathrm{M}}}-\frac{1}{\rho_{2}}\right\rceil \tag{1}
\end{equation*}
$$

Where $x_{i}, M_{i} \& \rho_{i}$ indicate the mole fraction, the molecular weight, density of the components and $\rho_{M}$ is the density of the mixture.

From density ( $\rho$ ) and flow time (t) the viscosity is determined by using the relation

$$
\begin{equation*}
\eta=\rho(\text { A. } t-\text { B. } t) \tag{2}
\end{equation*}
$$

Where, A \& B are the viscosity constants. Deviations in viscosity $(\Delta \eta)$ were obtained as

$$
\begin{equation*}
\Delta \eta=\eta_{\text {mix }}-\left(x_{1} \eta_{1}-x_{2} \eta_{2}\right) \tag{3}
\end{equation*}
$$

Where $\eta_{\text {mix }}$ is the viscosity of the mixture while $\eta_{1}$ and $\eta_{2}$ are the viscosities of pure components for first and second respectively. Linear regression analysis of a plot of $(\eta . t) / \rho$ against $t^{2}$ for pure water at four different temperatures provide the estimates of the constants ' $a$ ' and ' $b$ '.

## RESULTS AND DISCUSSIONS

CH exhibit confirmations and exists either in rigid chair form or in boat form and also in skew - boat form ${ }^{11}$ which undergo rapid inter conversion at room temperature which
leads to breaking up of hydrogen bonds ${ }^{12}$. A higher For the system $\mathrm{CH}+\mathrm{ET} \Delta \eta$ are negative over entire density or Viscosity of a molecule is due to higher intramolecular interactions ${ }^{13}$ experimental density and Viscosity values of binary liquid mixtures are summarized in Table -2 . The table shows decreasing trend in density and Viscosity for all three systems with increase in mole fraction ( $\mathrm{x}_{1}$ ) of CH. Fig. 1(a) shows the variation of $\mathrm{V}^{\mathrm{E}}$ with $\mathrm{x}_{1}(\mathrm{CH})$ for systems $\mathrm{CH}+$ Alkanols. For system CH +ET the $\mathrm{V}^{\mathrm{E}}$ shows both positive and negative values. Positive $\mathrm{V}^{\mathrm{E}}$ indicates the disruption of alkanol multimers through the breaking of hydrogen bonds while the negative $\mathrm{V}^{\mathrm{E}}$ value indicates the contraction of volume on mixing and its magnitude becomes more negative due to several attracting effects thus results in to the formation of new complex between CH and ET. It shows maxima at $x_{1} \approx 0.1$ and minima at $x_{1} \approx 0.9$. For $C H+P R$ system $V^{E}$ shows negative values over entire composition results from the attracting effects between them. It also shows maxima at $\mathrm{x}_{1} \approx 0.1$ and minima at $\mathrm{x}_{1} \approx 0.9$. For $\mathrm{CH}+$ BUT system the $\mathrm{V}^{\mathrm{E}}$ values are negative and becomes more negative as concentration increases. The negative $\mathrm{V}^{\mathrm{E}}$ values for the binary mixtures follow the decreasing order as $\mathrm{CH}+\mathrm{ET}>\mathrm{CH}+\mathrm{PR}>\mathrm{CH}+\mathrm{BUT}$.
Fig.2(a) represents $\mathrm{V}^{\mathrm{E}}$ with mole fraction ( $\mathrm{x}_{1}$ ) of CH for the systems $\mathrm{CH}+\mathrm{ETH} /$ aromatic ethers. The system $\mathrm{CH}+$ ETH shows negative $\mathrm{V}^{\mathrm{E}}$ values and becomes more negative as the concentration increases it shows maxima at $x_{1} \approx 0.1$ while minima at $x_{1} \approx 0.9$. For the system $\mathrm{CH}+$ THF the $\mathrm{V}^{\mathrm{E}}$ shows both positive and negative values Positive $\mathrm{V}^{\mathrm{E}}$ value indicates the decrease in double bond character and negative $\mathrm{V}^{\mathrm{E}}$ value indicates the increase in attraction of CH and becomes more negative as the concentration of CH increases. It shows maxima at $\mathrm{x}_{1} \approx 0.1$ while minima at $\mathrm{x}_{1} \approx 0.9$. The negative $\mathrm{V}^{\mathrm{E}}$ values for the binary mixtures follow the decreasing order as $\mathrm{CH}+$ ETH $>\mathrm{CH}+$ THF. It concludes that there is strong interaction between $\mathrm{CH}+\mathrm{ETH}$ than $\mathrm{CH}+\mathrm{THF}$.

Fig. 3(a) represents $\mathrm{V}^{\mathrm{E}}$ with mole fraction ( $\mathrm{x}_{1}$ ) of CH for the system $\mathrm{CH}+$ substituted aromatic rings. For the system $\mathrm{CH}+\mathrm{TE}$ the $\mathrm{V}^{\mathrm{E}}$ value shows both positive and negative values. The negative $\mathrm{V}^{\mathrm{E}}$ value results in the interaction between $\pi$ electron of TE and CH . Hence it shows attraction between them it shows maxima at $\mathrm{x}_{1} \approx 0.1$ while minima at $\mathrm{x}_{1} \approx 0.9$. For $\mathrm{CH}+\mathrm{m}-\mathrm{Xy}$ the $\mathrm{V}^{\mathrm{E}}$ values are negative over entire composition range results in the interaction between $\pi$ electron of $\mathrm{m}-\mathrm{Xy}$ and CH which shows attraction between them. The negative $\mathrm{V}^{\mathrm{E}}$ values with increasing concentration of $\mathrm{x}_{1}(\mathrm{CH})$ for the binary system follow the decreasing order as $\mathrm{CH}+\mathrm{m}-\mathrm{Xy}>\mathrm{CH}+$ TE.

Fig. 4(a) represents $\mathrm{V}^{\mathrm{E}}$ with mole fraction ( $\mathrm{x}_{1}$ ) of CH for the system $\mathrm{CH}+\mathrm{DMF}$ the $\mathrm{V}^{\mathrm{E}}$ value shows both positive and negative values as the concentration of CH increases the $\mathrm{V}^{\mathrm{E}}$ values become more negative results in the attraction between them due to the formation of hydrogen bond. It shows maxima at $x_{1} \approx 0.1$ and minima at $x_{1} \approx 0.9$. Fig. 1(b) represents variation of $\Delta \eta$ with $\left(x_{1}\right)$ for binary mixtures of $\mathrm{CH}+$ alkanols.
composition range which shows maxima at $x_{1} \approx 0.9$ and minima at $x_{1} \approx 0.5$ as it becomes more negative from $x_{1} \approx$ 0.1 to $x_{1} \approx 0.5$ clearly results due to the presence of attractive forces between them. For the system $\mathrm{CH}+\mathrm{PR}$ $\Delta \eta$ are negative and increases from $x_{1} \approx 0.0$ to $x_{1} \approx 0.4$ results due to the attraction between them. It shows maxima at $\mathrm{x}_{1} \approx 0.9$ while minima at $\mathrm{x}_{1} \approx 0.4$. For $\mathrm{CH}+$ BUT $\Delta \eta$ shows positive and negative values and as concentration increases $\Delta \eta$ value becomes more negative from $x_{1} \approx 0.2$ to $x_{1} \approx 0.6$ resulting from the attracting forces between them it shows maxima at $x_{1} \approx 0.1$ while minima at $x_{1} \approx 0.6$. The positive $\Delta \eta$ values for the binary mixtures follow the decreasing order has $\mathrm{CH}+\mathrm{ET}>\mathrm{CH}+\mathrm{PR}>$ $\mathrm{CH}+\mathrm{BUT}$.

Fig. 2(b) represents variation of $\Delta \eta$ with mole fraction ( $\mathrm{x}_{1}$ ) for binary mixtures of $\mathrm{CH}+\mathrm{ETH}$ /aromatic ethers for CH + ETH system the $\Delta \eta$ values are negative over entire composition range shows minima at $\mathrm{x}_{1} \approx 0.7$ while maxima at $x_{1} \approx 0.1$. For $\mathrm{CH}+$ THF $\Delta \eta$ values are also negative and becomes more negative as concentration increases from $\mathrm{x}_{1} \approx 0.1$ to $\mathrm{x}_{1} \approx 0.8$ results from $\pi$ electron donation from THF to CH . It shows maxima at $\mathrm{x}_{1} \approx 0.1$ while minima at $x_{1} \approx 0.8$. The negative $\Delta \eta$ values for the binary mixtures follows the decreasing order as $\mathrm{CH}+\mathrm{ETH}>\mathrm{CH}+\mathrm{THF}$. It concludes that there is strong interaction between $\mathrm{CH}+$ ETH than CH + THF.

Fig 3(b) represents variation of $\Delta \eta$ with mole fraction ( $x_{1}$ ) for binary mixtures of $\mathrm{CH}+$ substituted aromatic rings. For $\mathrm{CH}+\mathrm{TE} \Delta \eta$ values are negative clearly indicates the $\pi$ electron donation takes place from TE to CH It shows maxima at $\mathrm{x}_{1} \approx 0.1$ while minima at $\mathrm{x}_{1} \approx 0.7,0.8$. For $\mathrm{CH}+$ $\mathrm{m}-\mathrm{Xy} \Delta \eta$ values are negative over the entire composition range indicates the $\pi$ electron donation from $\mathrm{m}-\mathrm{Xy}$ to CH which shows maxima at $\mathrm{x}_{1} \approx 0.2$ and minima at $\mathrm{x}_{1} \approx 0.7$.

The negative $\Delta \eta$ values for the binary mixtures follow the decreasing order as $\mathrm{CH}+\mathrm{m}-\mathrm{Xy} \geq \mathrm{CH}+\mathrm{TE}$. It concludes that there is slight effect of addition of alkyl substituent on aromatic ring in presence of CH .

Fig. 4(b) represents variation of $\Delta \eta$ with mole fraction ( $x_{1}$ ) for binary mixture $\mathrm{CH}+$ DMF $\Delta \eta$ values becomes positive after $x_{1} \approx 0.3$ and its magnitude is more indicates specific interaction between $\mathrm{CH}+$ DMF shows presence of weak hydrogen bonding between them. It shows maxima at $\mathrm{x}_{1} \approx$ 0.5 while minima at $x_{1} \approx 0.3$.

Regression result for $\mathrm{V}^{\mathrm{E}} \& \Delta \eta$ of binary liquids at various temperatures along with the correlation coefficient $\left(\mathrm{R}^{2}\right)$ are illustrated in Table. 3

The dependence of $V^{E} / \Delta \eta$ on $x_{1}$ has been established using a polynomial equation as:-
$V^{E} / \Delta \eta=\sum A_{i} X_{i}^{i}(i=0,1,2,3)$
The coefficients $\mathrm{A}_{\mathrm{i}}$ along with the correlation coefficient $\mathrm{R}^{2}$ are listed in Table.3.

## CONCLUSIONS

For the system $\mathrm{CH}+$ alkanols the homo intermolecular Hydrogen bond between the alkanols weakens strongly due to the addition of CH (For short chain alkanols) resulting into the formation of new complex between them. As chain length of alkanols increases the hydrogen bonding decreases. For the system $\mathrm{CH}+$ substituted aromatic ring some interactions are present between them due to $\pi$-electron donation from aromatic ring to CH but it will remains unaffected as the alkyl substituent on aromatic ring are increases. For the system CH + ETH / aromatic ethers strong interaction is present between them due to the formation of Hydrogen bond as well as $\pi$ electron donation from aromatic ethers to CH . For the system CH + DMF some interactions are observed due to the presence of weak hydrogen bond in between them.

## ACKNOWLEDGEMENT

Y.B.VISPUTE owe sincere thanks to Principal Dr. D.F. Shirude, M.S.G. College, Malegaon Camp for granting the permission to avail the laboratory facility, Prof. Vijay Bhat, Principal MET'S Institute of TechnologyPolytechnic, Nashik for granting the required facilities time to time support for the completion of work. Author is also thankfu 1 to Prof. A.V. Kokate, MET'S Institute of Technology-Polytechnic, Adgaon, Nashik for encouragement during the work.
