Abstract: We study central automorphisms of free center-by metabelian Lie algebras. Our main result exhibits the form of such automorphisms.

Keywords: Central Automorphism, Center-by-metabelian, Lie algebra

## **I.INTRODUCTION**

Let F be the free Lie algebra with two free generators x an y over a field K, and let L be the free center-by-metabelian Lie algebra F/[F'',F]. Clearly L is freely generated by is an automorphism. the set  $\{\bar{x}, \bar{y}\}$ , where  $\bar{x} = x + [F'', F], \bar{y} = y + [F'', F]$ . We write x, y instead of  $\bar{x}, \bar{y}$ . By Aut(L) we denote the automorphism group of all automorphisms of L. Definition

Let  $\theta \in Aut(L)$ . If  $\theta$  induces the identity mapping on the algebra  $\frac{L}{Z(L)}$  then it is called a central automorphism of L, where Z(L) is the center of L. If  $\theta$  is a central automorphism of L then for every  $u \in L$  we have  $\theta(u) - u \in Z(L)$ . It can be easily seen that Z(L) = $\left| \left| F_{F}^{''}, F \right| \right|$ . Hence form of any central automorphism of L is

$$\theta(x) = x + u, \ \theta(y) = y + v, \qquad u, v \in L''$$

For any  $g, h \in L$  we write

$$[g, h^n] = [g, \underbrace{h, \dots h}_{n-times}].$$

A basis in L'' is formed by the elements

$$\left[ \left[ [g, y], x^{n_1}, y^{n_2} \right], [x, y] \right], \quad (n_1, n_2 \ge 0), \tag{1}$$

where  $g \in L$  and the sum  $n_1 + n_2$  is odd. (See [1], [7] and [8] for details).

Although there are many publications about central automorphisms of groups [2,3,4,5,6] the corresponding problems for relatively free Lie algebras are very rare. In [9], Ekici and Öztekin have given some characterizations of central automorphisms of free nilpotent Lie algebras.

In this work we prove that the following results.

Proposition

In the center-by-metabelian Lie algebra L every map  $\varphi: L \to L$  defined by

$$\varphi: x \to x + \sum \alpha_g \left[ \left[ [g, y] x^{m_1}, y^{m_2} \right] [x, y] \right] \quad \alpha_g \in K, g$$
  
 
$$\in L$$

$$x \rightarrow x + \sum \beta_h \left[ \left[ [h, y] x^{t_1}, y^{t_2} \right] [x, y] \right] \quad \beta_h \in K, h \in L$$

Proof

It can be easily seen that the Jacobian matrix of  $\varphi$  is invertible over U(L/L). Hence  $\varphi$  is an automorphism.

Theorem

Any central automorphism  $\theta$  of L has the form

$$\theta: x \to x + \sum_{n_1, n_2} \alpha_g \left[ g, \left[ \left[ \left[ [x, y], y^{n_2}, ]x^{n_1} \right], y \right] \right], \qquad (2)$$
  
 
$$y \to y + \sum_{n_1, n_2} \beta_h \left[ g, \left[ \left[ \left[ [x, y], y^{n_2}, ]x^{n_1} \right], y \right] \right]$$

where,  $g, h \in L'$ ,  $\alpha_q$ ,  $\beta_h \in K$ ,  $n_1 + n_2$ ,  $r_1 + r_2$  are odd. Proof

Let  $\theta$  be a central automorphism of L. Then it has the form

$$\begin{aligned} \theta \colon x \to x + u, \\ y \to y + v, \end{aligned}$$

Where  $u, v \in L''$ . Then the Lie algebra L'' has a linear basis of the form (1). Thus, the elements u, v can be written as linear combinations of elements of the form (1). Therefore we define  $\theta$  as

$$\begin{aligned} \theta : x &\to x + \sum_{n_1, n_2} c_g \left[ \left[ \left[ [g, y], x^{n_1} \right], y^{n_2} \right], [x, y] \right], \\ y &\to y + \sum_{r_1, r_2} d_h \left[ \left[ \left[ [h, y], x^{r_1} \right], y^{r_2} \right], [x, y] \right], \end{aligned}$$

where  $g, h \in L/_{L''}$ ,  $c_g, d_h \in K$ . Now let us apply the Jacobi identity to the elements

$$\left[\left[\left[g, y\right], x^{n_1}\right], y^{n_2}\right], [x, y]\right]$$
 and  $\left[\left[\left[h, y\right], x^{r_1}\right], y^{r_2}\right], [x, y]\right]$ 

consecutively we obtain

$$u = \left[ \left[ [g, y], x^{n_1}], y^{n_2} \right], [x, y] \right] \\= \left[ g, \left[ \left[ [x, y], y^{n_2}], x^{n_1} \right], y \right] \right]$$

And

$$v = \left[ \left[ \left[ [h, y], x^{r_1} \right], y^{r_2} \right], [x, y] \right] = \\ \left[ h, \left[ \left[ \left[ [x, y], y^{r_2} \right], x^{r_1} \right], y \right] \right].$$

Since  $u, v \in L''$  we see that the elements g and h have to belong L'. Therefore  $\theta$  has the form

$$\begin{aligned} \theta \colon x \to x + \sum_{n_1, n_{2 \ge 0}} \alpha_g \left[ g, \left[ \left[ \left[ [x, y], y^{n_2} \right], x^{n_1} \right], y \right] \right], \\ y \to y + \sum_{r_1, r_{2 \ge 0}} \beta_h \left[ h, \left[ \left[ \left[ [x, y], y^{r_2} \right], x^{r_1} \right], y \right] \right], \end{aligned}$$

where  $g, h \in L'$ ,  $\alpha_g, \beta_h \in K$ .

### Lemma

Let  $\theta \in Aut(L)$ . If  $[\theta(\omega), \omega] = 0$  for all  $w \in L$ , then it is central.

Proof

Let  $\theta \in Aut(L)$  such that  $[\theta(\omega), \omega] = 0$  for all  $\omega \in L$ . We define  $\theta$  as

$$\theta: x \to \alpha x + \beta y + u \\ y \to \gamma x + \delta y + v,$$

where  $u, v \in L', \alpha, \beta, \gamma, \delta \in K$ . By the assumption

$$\begin{aligned} [\theta(x), x] &= \beta[y, x] + [u, x] = 0, \\ [\theta(y), y] &= \gamma[x, y] + [v, y] = 0, \end{aligned}$$

These equalities lead  $\beta = \gamma = 0$ . Hence  $\theta$  has the form

$$\begin{aligned} \theta : x \to \alpha x + u, \\ y \to \delta y + v. \end{aligned}$$
  
From the equalitiy  $[\theta(x + y), x + y] = 0$  we get

$$0 = [\alpha x + u + \delta y + v, x + y]$$
  
=  $\alpha[x, y] + [u, x] + [u, y] + \delta[y, x] + [v, x] + [v, y]$   
=  $(\alpha - \delta)[x, y] + [u, x + y] + [v, x + y].$ 

Hence 
$$(\alpha - \delta) = 0$$
. Thus  $\theta$  has the form  
 $\theta: x \to \alpha x + u,$   
 $y \to \alpha y + v,$ 

where  $\alpha \neq 0$ .

Since  $\theta \in Aut(L)$  then

$$[\theta(x), \theta(y)] \equiv \alpha^2[x, y](mod[F', F]).$$
(3)

Copyright to IARJSET

Let us calculate  $[\theta(x), \theta(y)]$ .

 $[\theta(x), \theta(y)] = [\alpha x + u, \alpha y + v]$ =  $\alpha^{2}[x, y] + \alpha[x, v] + \alpha[u, y] + [u, v]$ 

By (3) we get  $\alpha([x, v] + [u, y]) + [u, v] \in [F', F].$ 

Hence  $u, v \in F''$ . Now consider the element  $\omega = x - [x, y]$ .

> $0 = [\theta(\omega), \omega]$ =  $[\theta(x) - [\theta(x), \theta(y)], \omega]$ =  $[\alpha x + u - [\alpha x + u, \alpha y + v], \omega]$ =  $[\alpha x + u - \alpha^2[x, y], x - [x, y]]$ =  $-\alpha[x, [x, y]] - \alpha^2[[x, y], x]$ =  $(\alpha - \alpha^2)[[x, y], x]$

Thus 
$$\alpha = 1$$
. Therefore  $\theta$  has the form  $\theta: x \to x + u$ ,

 $y \rightarrow y + v$ ,

where  $u, v \in L''$ .
